

**Data Structures Lab**  
**Session 10**

**Course:** Data Structures (CS2001)

**Instructor:**

**Semester:** Fall 2022

**T.A:** N/A

---

**Note:**

- Lab manual covers the following topics  
{AVL & its Rotations, basic utility functions }
- Maintain discipline during the lab.
- Just raise your hand if you have any problems.
- Completing all tasks of each lab is compulsory.
- Get your lab checked at the end of the session.

**AVL TREE:**

AVL tree is a self-balancing Binary Search Tree (BST) where the difference between heights of left and right subtrees cannot be more than one for all nodes. The valid BF range lies in { -1, 0, +1. In an AVL tree, every node maintains extra information known as the balance factor.

<pre>class TreeNode { public:     int value;     TreeNode * left;     TreeNode * right;      TreeNode() {         value = 0;         left = NULL;         right = NULL;     }      TreeNode(int v) {         value = v;         left = NULL;         right = NULL;     } }</pre>	<pre>class AVLTree { public:     TreeNode * root;      AVLTree() {         root = NULL;     }      bool isTreeEmpty() {         if (root == NULL) {             return true;         } else {             return false;         }     } }</pre>
--	---

**Balance Factor:**

The balance factor of a node is the difference between the heights of the left and right subtrees of that node. The balance factor of a node is calculated by subtracting the height of the right subtree from the height of the left subtree (OR) height of the right subtree - the height of the left subtree.

In the following explanation, we calculate balance factor of the tree as follows:

$$H = 2$$

BF for Right Subtree:  
 $H(\text{left leaf}) - H(\text{right leaf})$   
 $BF = 0 - 0$   
 $BF = 0$

```
// Get Balance factor of node N
int getBalanceFactor( TreeNode
* node) {
    if (n == NULL)
        return -1; // showing no node
is present in the tree or leaf node
        return height(node's left) -
height(node's right);
    }
}
```

Consider the Following Binary Search Tree now:

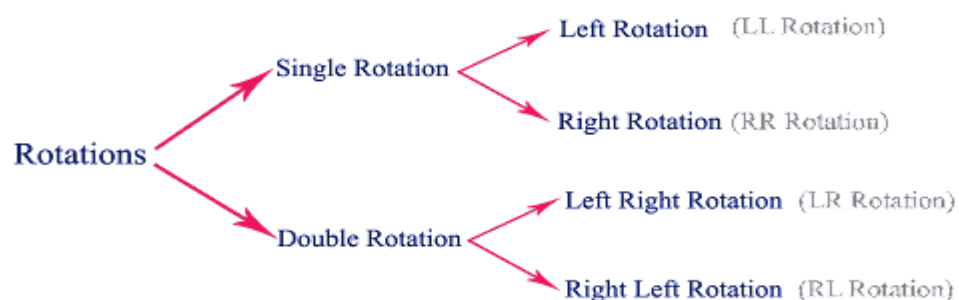

The balance factors for all of the subtrees and complete tree lie in the range of { 1, 0, -1 }  
 If in case we insert a new node: 4 into the left of node 1: 50, then:

Although the overall balance factor of BST is balanced, however, if you see, the left subtree starting from 25, it has a balance factor of +2, which means it is quite left heavy. To make it balanced, we have to perform some form of rotation:

### The AVL Tree Rotations :

In the AVL tree, after performing operations like insertion and deletion we need to check the balance factor of every node in the tree. If every node satisfies the balance factor condition then we conclude the operation otherwise we must make it balanced. Whenever the tree becomes imbalanced due to any operation we use rotation operations to make the tree balanced. Rotation operations are used to make the tree balanced. There are four rotations and they are classified into two types.

### Single Left Rotation (LL Rotation):

In LL Rotation, every node moves from one position to the left from the current position. To understand LL Rotation, let us consider the following insertion operation in AVL Tree.

insert 1, 2 and 3

Tree is imbalanced

To make balanced we use LL Rotation which moves nodes one position to left

After LL Rotation Tree is Balanced

## Single Right Rotation (RR Rotation)

In RR Rotation, every node moves from one position to the right from the current position. To understand RR Rotation, let us consider the following insertion operation in AVL Tree.

insert 3, 2 and 1

Tree is imbalanced  
because node 3 has balance factor 2

To make balanced we use RR Rotation which moves nodes one position to right

After RR Rotation Tree is Balanced

## Left Right Rotation (LR Rotation)

The LR Rotation is a sequence of single left rotation followed by a single right rotation. In LR Rotation, at first, every node moves one position to the left and one position to the right from the current position. To understand LR Rotation, let us consider the following insertion operation in AVL Tree.

insert 3, 1 and 2

Tree is imbalanced  
because node 3 has balance factor 2

LL Rotation

After LL Rotation

RR Rotation

After RR Rotation

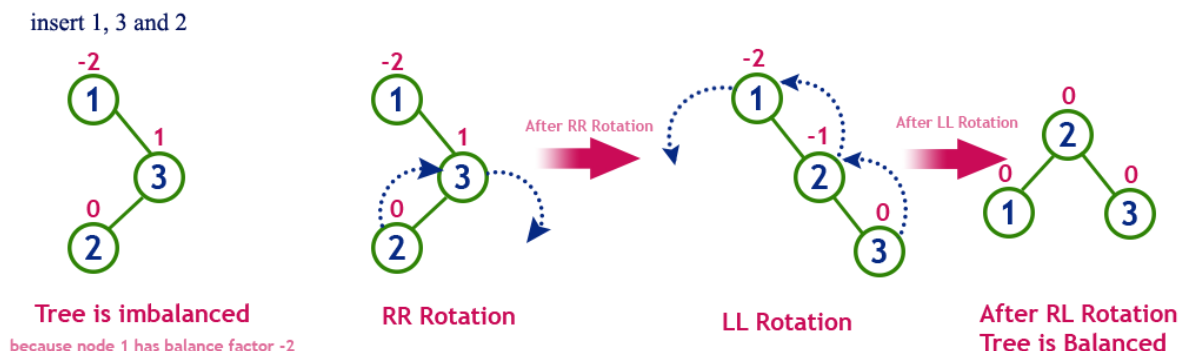

After LR Rotation Tree is Balanced

## Right Left Rotation (RL Rotation)

The RL Rotation is a sequence of single right rotation followed by a single left rotation. In

RL Rotation, at first, every node moves one position to the right and one position to the left from the current position. To understand RL Rotation, let us consider the following insertion operation in AVL Tree

```
TreeNode *
leftRotate(TreeNode * x)
{
    //temporary node pointers
    TreeNode * n1 = node's
    right;
    TreeNode * n2 = n1's
    left;

    // Perform rotation
    n1's left = x;
    x's right = n2;

    return n1;
}
```

```
TreeNode *
rightRotate(TreeNode * y)
{
    TreeNode * n1 = y's left;
    TreeNode * n2 = n1's
    right;

    // Perform rotation
    n1's right = y;
    y's left = n2;

    return n1;
}
```

## Operations on an AVL Tree

The following operations are performed on the AVL tree.

1. Insertion
2. Search
3. Deletion

### Insertion:

In an AVL tree, the insertion operation is performed with  $O(\log n)$  time complexity. In AVL Tree, a new node is always inserted as a leaf node. The insertion operation is performed as follows :

**Step 1** - Insert the new element into the tree using Binary Search Tree insertion logic.

**Step 2** - After insertion, check the Balance Factor of every node.

**Step 3** - If the Balance Factor of every node is 0 or 1 or -1 then go for the next operation.

**Step 4** - If the Balance Factor of any node is other than 0 or 1 or -1 then that tree is said to be imbalanced. In this case, perform suitable Rotation to make it balanced and go for the next operation

**Task-01:** Create an AVL Tree using insertion sequence as { 55, 66, 77, 11, 33, 22, 35, 25, 44, 88,99 },

the program should print the height of tree too.

### **Search Operation ion AVL Tree:**

In an AVL tree, the search operation is performed with  $O(\log n)$  time complexity. The search operation in the AVL tree is similar to the search operation in a Binary search tree. We use the following steps to search an element in the AVL tree.

**Step 1** - Read the search element from the user.

**Step 2** - Compare the search element with the value of the root node in the tree.

**Step 3** - If both are matched, then display "Given node is found!!!" and terminate the function

**Step 4** - If both are not matched, then check whether the search element is smaller or larger than that node value.

**Step 5**- If the search element is smaller, then continue the search process in the left subtree.

**Step 6** - If the search element is larger, then continue the search process in the right subtree.

**Step 7** - Repeat the same until we find the exact element or until the search element is compared with the leaf node.

**Step 8** - If we reach the node having the value equal to the search value, then display "Element is found" and terminate the function.

**Step 9** - If we reach the leaf node and if it is also not matched with the search element, then display "Element is not found" and terminate the function.

The implementation of the Search Operation is given below:

**Task-02:** Search the nodes having values in(66, 22, 44) in the tree constructed above.

### **Deletion Operation in AVL Trees:**

The deletion operation in AVL Tree is similar to the deletion operation in BST. But after every deletion operation, we need to check with the Balance Factor condition. If the tree is balanced after deletion goes for the next operation otherwise perform suitable rotation to make the tree balanced.

**Task-03:** Delete the nodes 35 and 99 from the tree, recalculate the bf and perform rotations to balance the tree.

**Task-04:** Print the resultant tree in pre, post, and in order.
